

Snapshot Feature Enhancement: Managed Package Permissions

Prior to February 5, 2016 any customizations that were done to Packaged Objects would be captured in a snapshot along with regular objects. This allowed users to migrate custom fields, and other changes to those objects quickly and easily. Unfortunately, no security was captured for those objects, even when migrating Profiles together. This meant many post deployment steps to add Object Permissions and Field Level Security for each profile.

On Saturday, February 5th, a change was made that fills this void. Now, users must select the package they wish to back up from the list of "Packages". Even if customized, they will no longer appear for backup in the "Objects" column. See the screen shot below.

Because of this change, when profiles are selected, the security for these packaged objects is also migrated. While it is more time consuming to build a snapshot this way (especially for a package that contains hundreds of objects and tabs) it is more thorough and actually saves you time by saving the post deployment steps of adding Object Permissions, and Field Level Security, etc. for all of your profiles. (It will also process more quickly if you don't need to grab the entire package).
